

TASK 5:

CASE STUDY

Phishing is a cybercrime in which a cybercriminal poses as a reputable organisation to obtain sensitive information (such as login details, bank account information, or other personal.

An example of phishing would be an email from someone claiming to be from your bank with an urgent matter requiring you to visit their website to update your account information. The criminal sends you a message indicating that because of some sort of urgency, such as a suspended account, you must click on a link to verify whether this is true, and then use it to connect through a fake website that appears identical to the actual website. Finally, the victim enters their banking information and login credentials on the fraudulent web page.

Phishing attacks are often directed at students, senior citizens, and individuals who are unfamiliar with cybersecurity, in addition to individuals using online banking or mobile payment services.

The consequences of phishing attacks can be severe, as victims may lose large sums of money, have their personal information stolen or compromised, or be subjected to identity theft. Victims may also be used to perpetrate future frauds, thus re-victimising individuals.

This case highlights the need for users to be aware of the potential for digital security problems. Users must carefully verify links before clicking on them; they should not provide any sensitive personal information over the web. Users should also enable two-factor authentication (2FA) to prevent becoming victims of phishing.
